Abstract

This data release constitutes the fourth public release by the Kilo-Degree Survey (KiDS). KiDS is an ESO public survey carried out with the VLT Survey Telescope and OmegaCAM camera, that will image 1350 square degrees in four filters (u, g, r, i), in single epochs per filter. KiDS was designed as a weak lensing shear tomography survey, and its core science drivers are mapping of the large-scale matter distribution in the universe and constraining the equation-of-state of Dark Energy. Additional science cases are manifold and range from galaxy evolution to Milky Way structure, and from detection of white dwarfs to high-redshift quasars.

This data release more than doubles the sky area covered by the first three releases combined, and for the first time includes photometry from the partner VIKING ESO public imaging survey on VISTA. For each of 1006 square-degree survey tiles the data release includes calibrated stacked images in u,g,r and i filters, their corresponding weights and masks, and single-band source lists extracted from the stacks. Furthermore, a multi-band ugriZYJHKs source catalogue is provided that encompasses the combined 1006 square degree area of this data release, with PSF-homogenised and aperture-matched photometry and photometric redshift estimates.

Figure 1: location of the 1006 KiDS-ESO-DR4 tiles. The area covered in DR1/2/3 is shown in blue, while the green tiles are new additions. The target 1350 sq.deg. KiDS survey area (top: KiDS-North; bottom: KiDS-South) is outlined in grey.

Overview of Observations
This data release (KiDS-ESO-DR4) consists of the coadded images, weight maps, masks and source lists of 1006 square degree survey tiles observed with OmegaCAM on the VST in u, g, r and i bands before January 24, 2018. It supercedes the 440 tiles released in DR1/2/3 (de Jong et al. 2015, A&A 582, A62; de Jong et al. 2017, A&A 604, A134). Figure 1 shows the DR4 footprint. Unlike the previous, incremental releases, for DR4 all data were reprocessed with improved astrometric and photometric calibration algorithms. The u,g,r and i images were reduced with the Astro-WISE system (McFarland et al. 2013, Exp.Astron., 35, 45).

In addition to these single-band data products, KiDS-ESO-DR4 includes a 9-band ugriYJHKs source catalogue that spans all survey tiles in the data release. It contains list-driven, aperture- and PSF-matched GAaP photometry from the stacked VST images, as well as from the VISTA pointings taken for the near-IR VIKING survey (Edge et al. 2013, The Messenger 154, 32). The included sources are detected on a separate reduction of the r-band stacks with the THELI pipeline (Erben et al. 2013, MNRAS 433, 2545), optimised for the weak lensing analysis. These r-band detection images are also included in the data release.

From the beginning, KiDS and VIKING were conceived together as a combined survey, covering the same parts of the sky. The VIKING survey started before KiDS, and was terminated in 2015 before completing the originally planned 1500 square degree footprint. It was therefore decided that KiDS observations would prioritise the 1350 square degrees for which VIKING data exist. At the time of writing it seems likely that KiDS will also conclude observations once the 1350 square degree VIKING footprint has been covered. The footprint area shown in grey in Figure 1 is this reduced area.
Release Content

Imaging products and single-band source lists

The list of 1006 tiles for which imaging data products and single-band source lists are included in KiDS-ESO-DR4 is provided online at http://kids.strw.leidenuniv.nl/DR4/data_table.php.

Each tile was observed in u, g, r, and i band. The final footprint of each tile is slightly larger than 1 square degree due to the dithering scheme: 61.9x65.4 arcminutes in u; 62.3x66.8 arcminutes in g, r and i. Taking this into account, the total sky coverage is approximately 993 square degrees (1022 if the edges of the footprint, where there are fewer dither exposures, are included). Compared to previous DR the sky coverage of the released data is significantly more contiguous, as illustrated in Figure 1.

The single-band source lists were extracted from the calibrated, stacked images for each tile and filter separately, using the Astro-WISE processing system. In addition, a second, weak lensing-optimised reduction of the r-band survey tiles using the THELI data reduction pipeline was performed, resulting in a separate r-band source list that is used for the 9-band photometry and (future) weak lensing analysis (these catalogues are described in the next section).

Since the OmegaCAM CCD mosaic consists of 32 individual CCDs, the sky covered by a single exposure has gaps. In order to fill in these gaps, KiDS tiles are built up from 5 dithered observations in g, r and i and 4 in u. The dithers form a staircase pattern with dither steps of 25″ in X (RA) and 85″ in Y (DEC), bridging the inter-CCD gaps (de Jong et al., 2015, A&A, 582, A62). The tile centres are based on a tiling strategy that tiles the full sky efficiently for VST/OmegaCAM. Neighbouring dithered stacks have an overlap in RA of 5% and in DEC of 10%.

In Figure 2 the obtained seeing (FWHM), PSF ellipticity, and limiting magnitude (5σ AB in 2″ aperture) distributions per filter are shown, to illustrate the obtained data quality. In case of the filters observed in dark time (u, g, r) the FWHM distributions reflect the different observing constraints, with r-band taking the best conditions. Since i-band is the only filter observed in bright time, it is observed under a large range of seeing conditions. Average PSF ellipticities are always small: <0.1 (the average is over the absolute amount of ellipticity, regardless of the direction of ellipticity). The wide range of limiting magnitudes in i-band is caused by the larger range in seeing and in moon phase and thus sky brightness.

A repeat pass of the full KiDS area in i band is underway, and will be included in a future release. These new data do not suffer from the poor baffling of the VST in the period up to May 2015 that particularly affected the i band sky background.

For a full overview of the data quality parameters for each observation we refer to the following online table: http://kids.strw.leidenuniv.nl/DR4/data_table.php.

The single-band tiles in this data release consists of 19.114 files and a total data size of 179Gb of catalogue data and 17Tb of pixel data (image, weight and mask).
Figure 2: Tile-by-tile raw data quality parameters for KiDS-ESO-DR4. **Left:** average PSF size (FWHM) distributions; centre: average ellipticity distributions (defined as 1-B/A, where A and B are the major and minor axis RMS length of the PSF); **right:** limiting magnitude distributions (5σ AB in 2” aperture). The distributions are per filter: from top to bottom u, g, r, and i, respectively.
9-band source catalogue

The KiDS-ESO-DR4 9-band source catalogue is based on the imaging data products described above, as well as new ZYJHK$_s$ near-IR photometry measured on the images from the overlapping VIKING survey on VIRCAM@VISTA. Here we provide a general description of the catalogue data, while an overview of all tiles with coordinates, PSF size, limiting magnitude, etc. is provided online: http://kids.strw.leidenuniv.nl/DR4/data_table.php.

The catalogue is based on the combined 1006 survey tiles, providing a total area coverage of approximately 1022 square degrees. The detection catalogue was generated from the r-band images reduced with the THELI pipeline. Those images form the basis for the weak lensing shape measurements, and this choice ensures that the definition of the sources in the photometric catalogue is consistent with the upcoming lensing catalogue (there was no such match between the DR3 photometric catalogue and the DR3.1 lensing catalogue, even though they were generated from the same raw data). The source coordinates and sizes were then used for forced (list-driven) ‘Gaussian Aperture and PSF (GAaP)’ photometry (Kuijken et al. 2015, MNRAS 454, 3500) on the Astro-WISE ugri VST images, and the ZYJHKs VISTA images reduced at the Cambridge Astronomical Survey Unit (CASU). The GAaP photometry for a source is effectively the integrated surface brightness over an elliptical Gaussian aperture function, defined on the intrinsic, seeing-deconvolved sky. It weights each part of the source consistently in each photometric band. Except for unresolved sources, it does not measure the total flux; instead the GAaP aperture size, shape and orientation it is optimised to return a high SNR flux for use in colour measurements. Error estimates on the GAaP fluxes are obtained by propagating the rms pixel noise through the measurement process.

The GAaP fluxes for the VST data were measured from the stacked u,gr and i images. For the VISTA data, where the gaps between detectors are larger and PSF variations across the field and from subexposure to subexposure greater, photometry was measured from individual summed jittered ‘paw-print’ images (see VIKING DR3 release description). Each source was typically detected 2-6 times per near-IR filter, and the 9-band catalogue reports the optimally-weighted average flux over all available subexposures containing that source.

The initial photometric calibration of the VST images is based on nightly zeropoints from photometric standard star fields observations. These are subsequently refined at catalogue level with stellar-locus regression and anchoring to the Gaia G band photometry (Brown et al. 2018, A&A 616, A1). The flux scales in the images correspond to the nightly zeropoints, with the catalogue-level corrections reported in the image header.

VIKING imaging is calibrated to 2MASS photometry (Skrutskie at al. 2006, AJ, 131, 1163) within CASU. This calibration is verified after photometry is measured by comparing individual stellar flux estimates per paw-print to SDSS z-band data (Alam et al. 2015, ApJS 219, 12) for the Z-band, colour converted SDSS z and 2MASS J data for the Y-band, and 2MASS JHK data for the JHKs bands respectively. Median offsets between 2MASS and VIKING photometry per observation are also calculated, to flag poorly calibrated observations.

For any given source, GAaP photometry requires the same aperture to be specified across all bands, and this aperture must not be smaller than the seeing. The GAaP aperture radii are set to the rms radii measured on the r-band detection image (SExtractor parameters A_WORLD and B_WORLD), quadratically added to a minimum radius chosen to optimize the SNR. To accommodate occasional poor seeing in one of the 9 bands, GAaP photometry was run with two choices of a minimum Gaussian aperture rms radius: 0.7” and 1.0”. When the seeing is good in all bands the smaller setting will yield the most accurate measurements, and this photometry is used. But for a band where the seeing is poor, the larger aperture may yield a more accurate flux, or the smaller
aperture may not yield a flux measurement at all. The choice of aperture radius is made source by source.

A detailed description of the VIKING GAaP photometry is provided in Wright et al. (ref).

The 9-band catalogue contains a total of 100.350.873 sources, is made up of 1007 files (1006 data files and 1 metadata file), and has a total data volume of 28.5 GB.
Release Notes

Data Reduction and Calibration
The KiDS-ESO-DR4 pipeline is an evolution of the KiDS-ESO-DR3 pipeline (de Jong et al, 2017, A&A 604, A134) (DJ17) and based on the Astro-WISE optical pipeline described in McFarland et al. (2013, ExA 35, 45) (MF13). Below we summarize the processing steps and list KiDS-specific information (i.e., KiDS process configuration and departures from Astro-WISE optical pipeline).

The main differences with the previous release are an improved astrometric calibration procedure, improved manual masking of satellite tracks, the separate r-band detection images produced with THELI that form the basis of the 9-band photometry catalogue, and the photometric calibration to the all-sky Gaia DR2 G band catalogue.

Image de-trending
De-trending of the raw data consists of the following steps.

- **Cross-talk correction.** Electronic cross-talk occurs between CCDs #93, #94, #95 and #96, resulting in faint imprints of bright sources on neighbouring CCDs. A correction was made for cross-talk between CCDs #95 and #96, where it is strongest (up to 0.7%).

- **De-biasing and overscan correction.** First, for each science and calibration exposure the overscan is subtracted per row (using method 6, see MF13). Second, a daily overscan-subtracted bias is subtracted. This is a daily average of 10 biases with 3σ-rejection.

- **Flat-fielding.** Whereas in the two previous data releases a single masterflat (per CCD and filter) was used for all data, changes to the telescope baffles in three steps during 2014/2015 necessitated the creation of new sets of masterflats. Table 1 lists the four different baffle configurations and the periods during which they were on the telescope.

*Table 1: VST baffle configurations*

For each baffling configuration a single masterflat (per CCD and filter) was used, by virtue of the stability of the intrinsic pixel sensitivities, that can be considered constant to ~0.2% or better for g, r and i (DJ15, Verdoes Kleijn et al., 2013, ExA, 35, 103). For g, r and i this master flat is a combination of a master dome (for high spatial frequencies) and master twilight (=sky) flat-field (for low spatial frequencies). Both contributing flats are an average of 5 raw flat-field exposures with 3σ-rejection. In u band only the twilight flats are used.

- **Illumination correction.** Illumination correction (a.k.a. "photometric superflat") is applied in pixel space, and only on the source fluxes (i.e., after background subtraction). A single illumination correction image is used to correct each masterflat (see also DJ15 and Verdoes Kleijn et al., 2013, ExA 35, 103). For baffling configuration 2, 3 and 4 illumination correction frames were derived from those for configuration 1, based on the difference between flatfields observed with each baffling configuration and with the original set-up.

- **De-fringing.** De-fringing is only needed for KiDS i-band. Analysis of nightly fringe frames showed that the pattern is constant in time. Therefore, a single fringe image was used for all KiDS-ESO-DR4 images observed after 2012-01-11. For each science exposure this
fringe image is scaled (after background subtraction of the science exposure and fringe frame) and then subtracted to minimize residual fringes.

- **Pixel masking.** Cosmic-rays, hot and cold pixels, saturated pixels are automatically masked as described in MF13 during de-trending. These are included in the weight image. Additional automatic and manual masking is applied on the coadds (see below).

- **Satellite track removal.** Satellite tracks are detected automatically by applying the Hough transform (Hough, 1962) to a difference image of maximally overlapping exposures within a dither sequence after masking bright stars and bright ghosts. The pixels affected by satellite tracks are masked and included in the weight image. Note: satellite tracks or parts thereof remaining after this automated step are masked during the coaddition stage, see below.

- **Background subtraction.** To remove vignetting by bond wire baffling (Iwert et al. 2006, Proc. SPIE 6276, 62760A) in the focal plane, a row-by-row background subtraction method is used, before the background subtraction done by SWARP (see below). Note: strong vignetting is not fully removed with this method and is masked during the coaddition stage, see below.

The THELI reductions of the r-band images are grouped in two-week ‘runs’ and new calibration frames are derived for each run. This includes illumination corrections, master flats, and biases. A more detailed description of the THELI processing will be given in Erben et al. (in preparation).

---

**Photometric calibration**

The steps taken to calibrate the photometry are as follows.

- KiDS-ESO-DR4 photometric calibration starts with individual zero-points per CCD based on secondary standard field observations. The calibration deploys a fixed aperture (6.3 arcsec diameter) not corrected for flux losses, and uses SDSS DR8 PSF magnitudes of stars in the SA fields as reference. Magnitudes are expressed in AB in the instrumental photometric system (i.e., no colour corrections between the OmegaCAM and SDSS photometric system applied).

- Next, the photometry in the g, r, and i filters is homogenized across CCDs and dithers for each filter in each tile independently. For u-band this homogenization is not applied because the relatively small source density often provides insufficient information to tie adjacent CCDs together. This global photometric solution is derived and applied in three steps:

  1. From the overlapping sources across dithered exposures, zero-point differences between the dithers (e.g. due to varying atmospheric extinction) are derived.

  2. Zero-point differences between CCDs are calculated using all CCD overlaps between the dithered exposures. Steps 1 and 2 both apply a minimization algorithm (see Maddox et al. 1990, MNRAS, 246, 433).

  3. The zero-point offsets are applied to all CCDs w.r.t. an average zero-point valid for the night, derived from the nightly SA field observations. If no SA field observations are available for the night, default values are used instead.

The above steps complete the photometric calibration of the image data and single-band source lists. A further homogenization of the photometry over the whole survey area is calculated using, and applied to, the multi-band source catalog, and is described below.
**Astrometry, regridding and coadding**
A global (multi-CCD and multi-dither) astrometric calibration is calculated per filter per tile. SCAMP (Bertin 2006, ASP Conf. Series 351, 112) is used for this purpose, with a polynomial degree of 3 over the whole mosaic, while an initial model is supplied to constrain the focal plane geometry. The (unfiltered) 2MASS-PSC (Skrutskie et al. 2006, AJ, 131, 1163) is used as astrometric reference catalogue.

SWARP is used to resample all exposures in a tile to the same pixel grid, with a pixel size of 0.2 arcseconds. After background subtraction the exposures are coadded using a weighted mean stacking procedure.

**Masking residual satellite tracks and bond wire baffling features**
Spurious features remaining in the coadded images are identified by visual inspection of 1500x1500 pixel 'thumbnails', at two levels of contrast, by a team of KiDS members. Missed or incompletely masked tracks that are caught at this stage are marked manually on thumbnail images, after which an automatic procedure identifies and masks the tracks in the correct subexposure(s).

Residual background features due to the bond wire baffles are flagged manually, triggering the creation of masks based on standard region files.

Individual CCDs showing electronic instability are also manually flagged and removed from the list of frames to be co-added.

Finally, using the updated masks, new stacks and corresponding weight images are produced.

**Masking of bright stars**
A stand-alone program dubbed Pulecenella v1.0 (DJ15) was developed to create masks for KiDS coadds, and is now embedded in the pipeline. It is an automatized procedure for mask creation completely independent from external star catalogues. An example of a detail of a mask is shown in Figure 3. Pulecenella detects the following types of critical areas, all related to bright stars:

- saturated pixels,
- spikes caused by diffraction by the mirror supports,
- readout spikes,
- reflection halos produced by the optics components (a central core halo, and up to three wider reflection halos with spatially dependent offsets, depending on the brightness of the star.)
Figure 3: Detail of a Pulecenella v1.0 mask. **Left:** detail of a KiDS stacked image with bright stars; critical areas detected by Pulecenella are over-plotted with green outlines. **Right:** FLAG image corresponding to the image shown on the left, with different colours indicating the pixel values resulting from the combination of different flag values.

The masks are provided as FITS FLAG images, where each type of critical region is identified by a different flag value, as listed in Table 2. During source extraction for the single-band source list (see below) the FLAG image is used to flag sources whose isophotes overlap with the critical areas. The resulting flags are stored in the following two source parameters:

- **IMAFLAGS_ISO:** FLAG image flags OR'd over the isophote profile
- **NIMAFLAG_ISO:** number of flagged pixels entering IMAFLAGS_ISO

Table 3: detection set-up for KiDS-ESO-DR4 single-band source lists

**Single-band source list extraction and star/galaxy separation**

The single-band source lists delivered in this data release are intended as "general purpose" source lists. Source list extraction and star/galaxy (hereafter S/G) separation is done with an automated procedure optimized for KiDS data: KiDS-CAT. This procedure, the backbone of which is formed by S-Extractor (Bertin & Arnouts, 1996, A&AS, 317, 393) performs the following steps:

1. S-Extractor is run on the stacked image to measure the FWHM of all sources. High-confidence star candidates are then identified (for details see La Barbera et al. 2008, PASP, 120, L681).
2. The average PSF FWHM is calculated by applying the bi-weight location estimator to the FWHM distribution of the high-confidence star candidates.
3. A second pass of S-Extractor is run with SEEING_FWHM set to the derived average PSF FHWM. During this second pass the image is background-subtracted, filtered and thresholded “on-the-fly”. Detected sources are then de-blended, cleaned, photometered, and classified. A number of S-Extractor input parameters are set individually for each image (e.g., SEEING_FWHM and GAIN), while others have been optimized to provide the best compromise between completeness and spurious detections (see the Data Quality section below). The detection set-up used is summarized in Table 3; a full SExtractor config file is available at this URL: [http://kids.strw.leidenuniv.nl/DR4/example_config.sex](http://kids.strw.leidenuniv.nl/DR4/example_config.sex)

Apart from isophotal magnitudes and Kron-like elliptical aperture magnitudes, a large number of aperture fluxes are included in the source lists. This allows users to estimate aperture corrections and total source magnitudes. All parameters provided in the source lists are listed in the Data Format section below.
4. S/G separation is performed based the CLASS_STAR (star classification) and SNR (signal-to-noise ratio) parameters provided by S-Extractor and consists of the following steps:
In the SNR range where the high-confidence star candidates are located (the red dots in Figure 4) the bi-weight estimator is used to define their CLASS_STAR location, θ, and its width, σ; a lower envelope of θ − 4σ is defined.

At SNR below that of the high-confidence star candidates, a running median CLASS_STAR value is computed from sources with CLASS_STAR > 0.8, which is shifted to match the θ − 4σ locus. The resulting curve (blue curve in Figure 4) defines the separation of stars and galaxies.

Figure 4: High-confidence star candidates and star/galaxy separation. Left: the high-confidence star candidates (red dots) are used to locate the stellar locus and calculate the average FWHM of the image. Right: example of star/galaxy separation; at SNR >50, the high-confidence star candidates (red dots) are used to define the blue line; at lower SNR, all sources with CLASS_STAR>0.8 are used; sources above the blue line are classified as stars.

The source magnitudes and fluxes in the final single-band source lists are not corrected for Galactic foreground or intergalactic extinction. The result of the S/G classification is available in the source lists via the 2DPHOT flag (SG2DPHOT in the multi-band catalog). Flag values are: 1 (high-confidence star candidates), 2 (objects with FWHM smaller than stars in the stellar locus, e.g., some cosmic-rays and/or other unreliable sources), 4 (stars according to S/G separation), and 0 otherwise (galaxies); flag values are summed, so 2DPHOT = 5 signifies a high-confidence star candidate that is also above the S/G separation line.

9-band source catalogue

Apart from the single-band VST data products, ESO-KiDS-DR4 also includes a matched-aperture photometry catalogue, containing 9 optical+near-infrared bands from a combined analysis of KiDS and VIKING. This catalogue is optimised for weak gravitational lensing science, and for this purpose an independent, high-accuracy astrometric analysis of the r-band images was performed using the THELI pipeline. Sources for the 9-band catalogue are detected on these 'detection images', and their positions used for list-driven photometry on the ugriz KiDS and ZYJHKs VIKING 'science' images. The THELI-reduced r-band detection images, as well as their associated weight and mask images, are part of DR4. Accurate galaxy shape measurements for the galaxies will be provided as a separate data product in a further release.

Sources are detected on the THELI r-band detection images using SExtractor, and source aperture positions and sizes are then used to perform GAap photometry on the KiDS (Astro-WISE) and VIKING (CASU) images. The detection setup is slightly different to the single-band Astro-
WISE setup in Table 3: the THELI setup uses DETECT_MINAREA=1, BACK_TYPE=MANUAL, BACK_VALUE=0,0,0,0 and DEBLEND_MINCONT=0.001. Note that the sources in this catalogue are not necessarily the same as those in the single-band r-band source lists described above. A number of morphological parameters are based on this SExtractor run, as well as GAaP fluxes, flux errors, and mask flags for each of the 9 bands. For each source the extinction in all nine filters is provided, interpolated from the extinction maps by Schlegel et al. (1998, ApJ, 500, 525), with updated extinction coefficients from Schlafly & Finkbeiner (2011, ApJ, 737, 103).

To prevent sources in tile overlaps from appearing multiple times in the catalogue, the survey tiles have been cropped to seamlessly connect to each other. Along the edges of survey tiles the data are less deep, but no worse than in the areas located in the gaps between the rows of CCDs in the focal plane, except along the outer edges of the contiguous areas. 9-band fluxes are reported for all r-band detections.

Seeing differences and aperture-matching

The catalogue includes magnitudes from the PSF homogenization and matched-aperture photometry “GAaP” pipeline. This novel technique is designed to account for PSF differences between different filters, while optimizing signal-to-noise. In short, the PSF within each coadded image is homogenized to a Gaussian shape without significantly degrading the seeing. Aperture photometry is then performed using elliptical Gaussian aperture weight functions, which are analytically corrected for seeing differences. A detailed description of the pipeline can be found in Kuijken et al. (2015, MNRAS, 454, 3500) (K15). It is important to note that these magnitudes are designed for deriving accurate colours of galaxies, not for total magnitudes of galaxies. For point sources (stars), GAaP magnitudes approach PSF-fitting photometry. The Gaussian aperture shape (Agaper, Bgaper) and orientation are set from the Sextractor A, B and PA measurements on the r-band detection image: Agaper=sqrt(MINAPER**2 + (A_WORLD*3600)**2), ditto B; values are maximised at MAXAPER=2”. Photometry for two GAaP runs, with MINAPER=0.7” and 1.0”, is reported in the catalogue (columns FLUX_GAAP_0p7_x and FLUX_GAAP_1p0_x, etc). The larger MINAPER value ensures valid measurements for those parts of the survey where the seeing in one of the bands was particularly poor.

Survey photometric homogenization

Zero-point corrections have been calculated for all ugrKIDS survey tiles included in the multi-band catalogue to improve the homogeneity of the photometry. These corrections are based on stellar locus regression (SLR). The SLR is used to calibrate the u, g and i filters to the r-band, and the latter is tied to Gaia DR2 using transformations derived from the overlap area between KiDS and SDSS.

The majority of stars display a well-defined photometric stellar locus: a tight relation in colour-colour space with a location that varies little across the sky outside the Galactic plane. SLR is the method where the observed stellar locus is matched to the fiducial intrinsic locus, and offers the possibility to achieve colour homogeneity. SLR was applied to the GAaP photometry of unmasked and not flagged, high S/N (mag_r-GAAP < 19) point sources (0.4” < FWHMr < 0.8”). Per source the GAaP magnitudes are corrected for Galactic extinction using the E(B-V) colour excess from Schlegel et al. (1998) and extinction coefficients from Schlafly & Finkbeiner (2011). The stellar locus is parametrized using the “principal colours” s, x and w as defined by Ivezic et al. (2004, AN, 325, 583). For each of these colours (projections that are linear combinations of the ugr filters), a
straight section of the stellar locus lies parallel to one axis (P1) and is centred at 0 on the other axis (P2), see Fig. 5. We add a fourth, redundant colour \(k\) as additional guard for fitting robustness. Per source the P1 and P2 are calculated in each colour and sources on the straight part of the stellar locus are selected using fixed limits in P1. The median P2 values in each tile are converted to zero-point offsets with respect to \(r\) (\(d(u-r), d(g-r), d(i-r)\)). Fig. 5 shows an example of a typical fit.

\[
\begin{align*}
\text{Figure 5: principal colours } & s,w,x \text{ and } k \text{ for tile KiDS_{129.0_0.5}. The same stars (yellow) are plotted in each panel, with the stars used to locate the straight sections of the locus shown in black. The inferred median P2 offsets’ formal errors and standard deviations are shown above each panel.}
\end{align*}
\]

Already in DR3 we concluded that \(u\) band calibration with the SLR techniques described above resulted in large errors, and the alternative approach of overlap photometry was used. For DR4 a different approach was used for the \(u\) band, a combination of SLR with a latitude-dependent correction term, obtained by fitting the extinction-corrected \(u\) band as a function of dereddened \((g-r)\) colour and galactic latitude over the SDSS region that overlaps with KiDS-N:

\[
u = g + 2.0(g-r)_0 + 0.456 + \max(0,0.66-2(g-r)_0) - 0.25 |\sin(b)| \quad (0.15<(g-r)_0<0.8)
\]

The \(u\)-band zeropoint of each KiDS tile is then adjusted until the median residual from this relation is zero.

The SLR yields a zero-point offset / correction per survey tile for each filter. The offsets as derived for band \(x\) are listed in the catalogue headers as \(D_x\_SLR\) and \(D_x\_SLR\_1\) for the MINA-PER=0.7 and 1.0 GAAp runs. The offsets are also listed online in the catalogue table. By definition, the \(r\)-band SLR offset is zero.
Figure 6. Illustration of the calibration of the r band photometry for tile KIDS_131.0_0.5 to the Gaia G band, using the dereddened KIDS (g-i) colours of stars with 16.5 < G < 19.25. The stars plotted in blue are used to determine the vertical location of the red box, which is centered on the relation derived from the SDSS-Gaia-KiDS overlap.

Calibration to Gaia-DR2 G band

With the advent of Gaia, a high-density, accurate photometric catalogue covering the whole sky has become available. Per tile typically 500-1000 Gaia stars were used to tie the r-band photometric zero point to the Gaia-DR2 G band calibration, using a fiducial dereddened (r-G) vs (g-i) colour-colour relation derived from the overlap of KiDS-North with the SDSS DR7 catalogue. The same offset is applied to u, g and i magnitudes as well, to preserve the SLR calibration. An example of this calibration is shown in Figure 6. These zeropoints are reported in the catalogue headers as DMAG_x and DMAG_x_1, for the MINAPER=0.7 and 1.0 GAaP runs, and are applied to the MAG_GAAP_0p7_x and MAG_GAAP_1p0_x magnitudes given in the catalogues. For each u gri image the zeropoint that is derived using the largest number of stars is recorded in the image header; the keyword CALMINAP records the corresponding value of MINAPER.

Near-infrared photometry from VIKING tied to 2MASS

VIKING photometry is calibrated to 2MASS during its processing. The GAaP fluxes in the 9-band catalogue use this calibration without change. All VIKING fluxes have magnitude zeropoint 30. More details are provided in Wright et al (2018).

Choice of GAaP aperture and extinction corrected magnitudes

Because the footprints of the VISTA and VST observations differ, the band-by-band seeing of the sources varies on scales smaller than a KiDS tile. The catalogue therefore provides a source-by-source choice between the MINAPER=0.7 and MINAPER=1.0 columns. The decision is based on the flux errors on the measurements of that source in all bands:

1. Define ERROR_RATIO_x = FLUXERR_GAAP_x_1p0 / FLUXERR_GAAP_0p7_x for each band x

2. If MAX(ERROR_RATIO_x)*MIN(ERROR_RATIO_x) < 1, use the larger (1p0) aperture.

This choice ensures that the larger aperture is only used if, for at least one band, it yields a fractional improvement in flux error that is greater than the fractional penalty in any other band.
The fluxes that correspond to this best aperture choice are recorded in the catalogues as $\text{FLUX}_{\text{GAAP},x}$, $\text{MAG}_{\text{GAAP},x}$, etc. The magnitudes are corrected for the photometric zero-point and galactic extinction:

$$\text{MAG}_{\text{GAAP},x} = \text{DMAG}_x - 2.5 \log_{10}(\text{FLUX}_{\text{GAAP},0.7,x}) - \text{EXTINCTION}_x$$

or

$$\text{MAG}_{\text{GAAP},x} = \text{DMAG}_x.1 - 2.5 \log_{10}(\text{FLUX}_{\text{GAAP},1.0,x}) - \text{EXTINCTION}_x$$

where the $\text{DMAG}_x$ and $\text{DMAG}_x.1$ values are those reported in the header for $x=u,g,r,i$, and equal to 30 for the VISTA $Z,Y,J,H,K_s$ bands.

(Note that the magnitudes $\text{MAG}_{\text{GAAP},0.7,x}$ and $\text{MAG}_{\text{GAAP},1.0,x}$ are NOT corrected for extinction)

**Extinction-corrected colours**

In order to facilitate faster catalogue searches, the catalogue includes columns with source colours between adjacent bands ($u-g$, $g-r$, ..., $J-H$, $H-K$). These colours are based on the GAaP magnitudes, which provide the most accurate colours both for galaxies and point sources. In these columns the zero-point corrections described above, as well as the per-source Galactic extinction corrections, are already applied.

**Photometric redshifts**

Based on the homogenized GAaP photometry, photometric redshifts have been calculated following the methods developed for CFHTLenS and described in K15. This makes use of the Bayesian photometric redshift code BPZ (Benítez, 2000, ApJ, 536, 571) in combination with the recalibrated templates from Capak (2004, PhD. thesis, Univ. Hawai‘i). A new prior distribution (Raichoor A., et al., 2014, ApJ, 797, 102) has been used for DR4, which is more effective at fainter magnitudes than the prior used for DR3, but is biased by ca. +0.06 at bright magnitudes. We also switched to 68% confidence intervals for the photo-z posterior (previous releases reported 95%). **We caution all users that for accurate work, the photometric redshifts should be used in conjunction with external calibration data in order to quantify their error distribution** (see, e.g. Hildebrandt et al. 2017, 465, 1454). The catalogue also includes the ODDS parameter, a measure of the uni-modality of the redshift PDF, and the best-fit template for each source (parameter $T_B$). The values correspond to the following types, where fractional types can occur because the templates are interpolated: 1=CWW-Ell, 2=CWW-Sbc, 3=CWW-Scd, 4=CWW-Im, 5=KIN-SB3, 6=KIN-SB2.
Data Quality
An overview of the intrinsic data quality of KiDS-ESO-DR4, in terms of seeing, PSF ellipticity, and limiting magnitudes distributions is presented in Fig. 2. In the following we focus on the quality of the reduced data products.

Photometric quality
The matter of photometric quality can be split up in two:
1. the uniformity of the photometry within each tile
2. the quality of the absolute photometric calibration per tile/filter

Both the internal photometric homogeneity within a coadd and the quality of the absolute photometric scale can be assessed by comparing the KiDS-ESO-DR4 photometry to SDSS DR8 (Aihara et al., 2011, ApJS, 193, 29). For this, PSF magnitudes were extracted from SDSS DR8 and compared to both the aperture-corrected and GAaP magnitudes in the KiDS-ESO-DR4 multi-band catalogue. Only stars with photometric errors both in KiDS and in SDSS smaller than 0.02 mag in g, r, and i or 0.03 in u were used. This comparison can be made only for all tiles in the KiDS-North field, but since KiDS-South was calibrated in the same way as KiDS-North, we expect the conclusions to hold for all data.

Figure 7 shows the offsets between KiDS aperture-corrected and SDSS DR8 magnitudes for 1 tile (KiDS_182.0_-0.5), which is a representative example. Generally, the photometry in a filter is uniform within one tile to within a few percent. In u-band the photometry may be less stable in some cases due to the lack of photometric homogenization within a tile.

Figure 7: KiDS – SDSS magnitude offsets for (unmasked) stars in tile KiDS 182.0_-0.5 vs RA (top panel) and DEC (bottom panel), based on aperture-corrected fluxes. From top to bottom the sub-panels correspond to u, g, r, and i, respectively. Each dot corresponds to a star, and the red dashed lines indicate +0.05 and −0.05 magnitudes.
Fig. 8: Photometric calibration and PSF sizes in KiDS-North. Average magnitude offsets for KiDS-ESO-DR3 tiles between KiDS GAaP magnitudes and SDSS DR8 PSF magnitudes of stars are indicated by the colour coding, while the symbol size corresponds to the average PSF size.

The quality of the absolute photometric scale is illustrated in Figure 8 and summarized in Table 4. Small systematic offsets of 2 to 3 % are present in all filters. This could be due to the fact that nightly zero-points are determined using a fixed aperture on stars in the SA field without aperture correction. The scatter and occasional outliers in the standard calibration are due to non-photometric conditions (during either KiDS or SA field observations) and, particularly in case of the u-band, use of default zero-points for nights without good SA field observations. Photometric inhomogeneities in SDSS, which is reliable to 1% in gri and 2% in u (Padmanabhan et al. 2008, ApJ, 674, 2) also contribute to the measured scatter.

Table 4: Average magnitude offsets and their standard deviation with respect to SDSS DR8 (for u,g,r,i) and expected stellar locus locations (in principal colours s,w,x) for GAaP and aperture-corrected (10") magnitudes, both before and after photometric homogenization.

The photometric homogenization scheme significantly improves the stability of the calibration and annihilates the outliers completely, with the possible exceptions of isolated tiles or very small contiguous groups without photometric anchors. Derived using GAaP magnitudes, the homogenization clearly works best when applied to the GAaP magnitudes. Given the photometric stability of SDSS quoted by Padmanabhan et al. (2008, ApJ, 674, 2), the standard deviations of the offsets to SDSS (second to last column in Table 4) imply that the stability of the calibration in the u-, g-, r- and i-bands is approximately 2%, 2%, 1% and 1%, respectively. Also when applied to the aperture-corrected magnitudes the stability of the calibration is significantly improved and outliers removed. The SLR step in the photometric homogenization procedure ensures that the stellar locus “principal colours” (bottom three rows in Table 4) are close to zero. Overall, the combination of GAaP magnitudes, extinction corrections and photometric homogenization produces the most accurate colours, both for stars and galaxies. Note that the colour columns in the multi-band catalogue already contain all these corrections, while the individual magnitude columns are not corrected for extinction and calibration variations!
**Colour terms**

The photometric calibration provided in KiDS-ESO-DR4 is in AB magnitudes in the instrumental system. We report here the colour-terms calculated with respect to the SDSS photometric system for DR3.

Aperture-corrected magnitudes taken from the multi-band catalogue, were matched to SDSS (DR8) PSF magnitudes of point-like sources. For each filter, the median offset to SDSS is first subtracted, rejecting tiles where this offset exceeds 0.1 mag in any of the g, r and i bands. The fit is made using all points from the remaining tiles. The resulting colour terms:

\[
\begin{align*}
UKIDS - USDSS &= (-0.050 \pm 0.002)(USDSS - gSDSS), \\
g_{KiDS} - g_{SDSS} &= (-0.052 \pm 0.002)(g_{SDSS} - r_{SDSS}), \\
r_{KiDS} - r_{SDSS} &= (-0.033 \pm 0.002)(g_{SDSS} - r_{SDSS}), \\
i_{KiDS} - i_{SDSS} &= (+0.012 \pm 0.002)(r_{SDSS} - i_{SDSS}).
\end{align*}
\]

**Known issues**

**Image defects**

**Scattered light and reflections**

Some of the main issues in the DR1/2/3 VST/OmegaCAM data (before the baffling improvements described above were made) are related to scattered light and reflections. Due to the open structure of the telescope, light from sources outside the field-of-view can affect the observations. This expresses itself in a number of ways:

- **Reflections**: in some cases strong reflected light patterns are seen in the focal plane; these are caused by light from bright point sources outside the field-of-view and can occur in all filters.

- **Vignetting by CCD masks**: vignetting and scattering by the masks present at the corners of the focal plane array, and at the gaps between the rows of CCDs; this effect is particularly strong in i-band due to the bright conditions. The effect near the CCD gaps is largely corrected for, but in many cases the areas in the corners of the CCD array is strongly affected.

- **Extended background artefacts**: related to the reflections mentioned before, this is mostly seen in i-band and probably caused by moonlight.

Improvements to the telescope baffles that were installed in 2014 and 2015 significantly improved scattered light suppression. The i-band observations, many of which were taken with the moon above the horizon, were particularly affected by scattered light; a second i-band pass is underway and these new data (which will form part of DR5) should have significantly lower and smoother backgrounds.

More detailed illustrations of some of the scattered light effects are provided in the Release Notes accompanying KiDS-ESO-DR3.
Previous Releases

The current release, KiDS public data release number 4 or KiDS-ESO-DR4, was preceded by data release numbers 1-3 (KiDS-ESO-DR1/2/3). It supersedes these earlier releases, representing a complete re-reduction of all KiDS tiles completed before January 24th, 2018. For a small number of tiles the automatic reduction failed in a way that could not easily be fixed, and in order not to delay DR4 these have been excluded from the delivery. They will be included in DR5. These missing tiles include five tiles (KIDS_39.6_-34.1, KIDS_338.8_-32.1, KIDS_340.0_-32.1, KIDS_340.2_-31.2, KIDS_343.5_-32.1) which processed without error in DR1+2+3, but which failed to yield a consistent astrometric solution in the DR4 pipeline (conversely, a much larger number of tiles that gave problems in the earlier processing passed through the DR4 reduction without problem).

Apart from the large increase in area, from 440 to 1006 square-degree tiles, the main enhancement of DR4 over the previous release is the inclusion of the VIKING photometry in the multi-band catalogue, and the homogeneous calibration of the KiDS data to Gaia through stellar locus regression.
**Data Format**

**Files Types**
Table 5 lists the types of data products provided in this release, together with descriptions of the file types and naming conventions used.

The naming convention used for all data products is the following:

\[ \text{KiDS\_DR4.0\_R.R\_D.D\_F\_TTT.fits} \]

where R.R and D.D are the RA and DEC of the tile centre in degrees (J2000.0) with 1 decimal place, F is the filter (u, g, r, or i for single-band data files, “ugriZyJHKs” for multi-band catalogue files), and TTT is the data product type (see column 4 of Table 5).

For example: the r-band stacked image of the tile “KIDS\_131.0\_0.5” is called 
\[ \text{KiDS\_DR4.0\_131.0\_0.5\_r\_sci.fits} \]

*Table 5: data products and file types*

**Format of coadded images**
The final calibrated, coadded images from the Astro-WISE pipeline have a uniform pixel scale of 0.2 arcsec. The pixel units are fluxes relative to the flux corresponding to magnitude = 0, as based on nightly photometric calibrations. This means that the effective zero-point is equal to 0 and the magnitude \( m \) corresponding to a pixel value \( f \) is:

\[
m = -2.5 \log_{10} f.
\]

Subsequent photometric zeropoint corrections were derived from the catalogues and recorded in the image headers using the DMAG keyword. The keywords CALSTARS and CALMINAP give the number of Gaia stars that were used in the calibration, and CALMINAP is the value of the GAAp MINAPER parameter (0.7 or 1.0) that was used for the photometry that resulted in this zero-point.

The r-band detection images, which result from a reduction using THELI, specifically designed for optimal image shape measurement and small astrometric reductions, are the basis of the multi-band catalogue. They have a pixel scale that is closer to the native OmegaCAM pixel size of 0.213". 
Catalogue Columns

Table 6 lists the columns that are present in the single-band source lists provided in KiDS-ESO-DR4. A large number (27) of aperture fluxes are provided to suit the needs of different users and allow interpolation to estimate e.g. aperture corrections. Only the columns for the smallest aperture (2 pixels, or 0.4 arcsec diameter) and the largest aperture (200 pixels, or 40 arcsec diameter) are listed in Table 6. Note: the label for the aperture of 28.5 pixels is FLUX_APER_28p5.

Table 7 lists the columns that are present in the multi-band source catalogue provided in KiDS-ESO-DR4. The meaning of the bits of the corresponding MASK values is explained in Table 8.

**Photometric redshift estimate**

- **Z_B** | ID | 9-band BPZ redshift estimate; peak of posterior probability distribution
- **Z_B_MIN** | ID | Lower bound of the 68% confidence interval of Z_B
- **Z_B_MAX** | ID | Upper bound of the 68% confidence interval of Z_B
- **T_B** | ID | Spectral type corresponding to Z_B
- **ODDS** | ID | Empirical ODDS of Z_B

30
### Z_ML 1D 9-band BPZ maximum likelihood redshift

### T_ML 1D Spectral type corresponding to Z_ML

### CHISQUARED_BPZ 1D chi-squared value associated with Z_B

### M_0 1D mag Reference magnitude for BPZ prior

### BPZ_FILT 1J filters with good photometry (BPZ)

### NBPZ_FILT 1J number of filters with good phot. (BPZ)

### BPZ_NONDETFILT 1J filters with faint photometry (BPZ)

### NBPZ_NONDETFILT 1J number of filters with faint phot. (BPZ)

### BPZ_FLAGFILT 1J flagged filters (BPZ)

### NBPZ_FLAGFILT 1J number of flagged filters (BPZ)
