Supernovae
the whole story (so far)
Briefly

- The FORSes Target of Opportunity science is dominated by Supernovae and GRBs;

- In the last 10 years SNe have been (re)gaining popularity over GRBs (but… sGRB regaining interest after the association to kilo-novae and GW events)
Why?

- Obvious high-throughput work-horses for photometry and low-resolution spectroscopy
- Efficient ToO/RRM activation
- [Unique polarimetric capabilities]
some [crude] stats

- keywords/title/abstract: supernova* “gamma-ray burst*”
  “gamma-ray burst*”
- visual inspection of output (results are very reasonable)
- 419 refereed papers (A&A 146; ApJ 140; Nature 14; Science 4)
- Total citations: 40,490

(Submitted on 22 Jun 1999)

Following a BeppoSAX alert (Piro 1999a) and the discovery of the OT at SAAO (Vreeswijk et al. 1999a), we observed GRB 990510 with the FORS instrument on ESO's VLT Unit 1 ('Antu'). The burst is unremarkable in gamma rays, but in optical is the first one to show good evidence for jet–like outflow (Stanek et al. 1999, Harrison et al. 1999). We report the detection of significant linear polarization in the afterglow: it is (1.6 +/- 0.2)% 0.86 days after trigger, and after 1.81 days is consistent with that same value, but much more uncertain. The polarization angle is constant on a time scale of hours, and may be constant over one day. We conclude that the polarization is intrinsic to the source and due to the synchrotron nature of the emission, and discuss the random and ordered field geometries that may be responsible for it.

Looking for the SN signature

Fig. 1. Lightcurves of the afterglow of GRB 000911. From top left to bottom right, the $J$, $I$, $R$, $V$ and $B$ lightcurves are plotted. The thick solid curves show the best fits obtained with our three component model. The dashed, dotted and dot-dashed lines show the SN, galaxy and ES components, respectively. The thin solid lines in the $J$, $I$ and $R$ panels indicate the best fit for a model comprising only the galaxy and ES (without SN). The thin line is indistinguishable from the thick solid line for the $V$ and $B$ filters.
The smoking gun...

A very energetic supernova associated with the gamma–ray burst of 29 March 2003

(Submitted on 17 Jun 2003)

Over the past five years evidence has mounted that long–duration (> 2 s) gamma–ray bursts (GRBs)––the most brilliant of all astronomical explosions––signal the collapse of massive stars in our Universe. This evidence was originally based on the probable association of one unusual GRB with a supernova, but now includes the association of GRBs with regions of massive star formation in distant galaxies, the appearance of supernova–like 'bumps' in the optical afterglow light curves of several bursts and lines of freshly synthesized elements in the spectra of a few X–ray afterglows. These observations support, but do not yet conclusively demonstrate, the idea that long–duration GRBs are associated with the deaths of massive stars, presumably arising from core collapse. Here we report evidence that a very energetic supernova (a hypernova) was temporally and spatially coincident with a GRB at redshift \( z = 0.1685 \). The timing of the supernova indicates that it exploded within a few days of the GRB, strongly suggesting that core–collapse events can give rise to GRBs, thereby favouring the 'collapsar' model.

SPECTROPOLARIMETRY OF THE TYPE Ic SUPERNOVA SN 2002ap IN M74: MORE EVIDENCE FOR ASYMMETRIC CORE COLLAPSE

Lifan Wang, Dietrich Baade, Peter Höflich, and J. Craig Wheeler

Received 2002 June 19; accepted 2003 March 19

ABSTRACT

High-quality spectropolarimetry (range 417–860 nm; spectral resolution 1.27 nm with 0.265 nm pixel$^{-1}$) of SN 2002ap was obtained with the ESO Very Large Telescope Melipal (+FORS1) at three epochs that correspond to −6, −2, +1, and +3 days for a $V$ maximum of 2002 February 9. The polarization spectra show three distinct broad (∼100 nm) features at ∼400, 550, and 750 nm that evolve in shape, amplitude, and orientation in the $Q-U$ plane. The continuum polarization grows from nearly zero to ∼0.5%. The 750 nm feature is polarized at a level ≥1%. We identify the 550 and 750 nm features as Na I D and O I 777.4 nm moving at about 20,000 km s$^{-1}$. The blue feature may be Fe II. The position angle of the continuum is ∼83°, and that of the O I line is ∼133°. This indicates that the $^{56}$Ni that provides the continuum luminosity is distributed with a systematically different geometry than that of the fast-moving outer oxygen structure. The lack of significant polarization prior to optical maximum indicates that the photosphere was not extremely highly distorted at early times but became more aspherical toward optical maximum. The structure is consistent with the impact of a bipolar flow from the core that has severely distorted, but is stopped within, the outer envelope of a carbon/oxygen core. The difference in position angle of the oxygen feature and the continuum demands a symmetry breaking that may be difficult to provide in a single-star model. This difference may be a clue to the binary nature of the progenitor. We conclude that the features that characterize SN 2002ap, specifically its high velocity, can be accounted for in an asymmetric model with a larger ejecta mass than SN 1994I such that the photosphere remains longer in higher velocity material. The characteristics of "hypernovae" may be the result of orientation effects in a mildly inhomogeneous set of progenitors, rather than requiring an excessive total energy or luminosity. In the analysis of asymmetric events with spherically symmetric models, it is probably advisable to refer to "isotropic equivalent" energy, luminosity, ejected mass, and nickel mass.
First direct evidence of chemical asymmetries in a Type Ia SN

take home

• The FORSes made a major contribution in the field of GRBs, and in the association between long-duration GRB and supernovae.

• They contributed to large-scale projects in the SN Type Ia/cosmology field (SN Legacy Survey, ESSENCE, SN Factory, …), in synergy with Gemini, Keck, Subaru, HST

• They generated a wealth of data for single SNe of all types
FORS in the GW era

• All started with the Ligo-Virgo O2 campaign

• The ESO community was ready to react, with approved ToO programmes on X-S, FORS2, ...

• X-Shooter played THE role: the spectral sequence is just a marvel in itself
First polarization measurements in a GW

The unpolarized macronova associated with the gravitational wave event GW170817

(Submitted on 16 Oct 2017)

The merger of two dense stellar remnants including at least one neutron star (NS) is predicted to produce gravitational waves (GWs) and short duration gamma ray bursts (GRBs). In the process, neutron-rich material is ejected from the system and heavy elements are synthesized by r-process nucleosynthesis. The radioactive decay of these heavy elements produces additional transient radiation termed "kilonova" or "macronova". We report the detection of linear optical polarization $P = (0.50 \pm 0.07)\%$ at 1.46 days after detection of the GWs from GW170817, a double neutron star merger associated with an optical macronova counterpart and a short GRB. The optical emission from a macronova is expected to be characterized by a blue, rapidly decaying, component and a red, more slowly evolving, component due to material rich of heavy elements, the lanthanides. The polarization measurement was made when the macronova was still in its blue phase, during which there is an important contribution from a lanthanide-free outflow. The low degree of polarization is consistent with intrinsically unpolarized emission scattered by Galactic dust, suggesting a symmetric geometry of the emitting region and low inclination of the merger system. Stringent upper limits to the polarization degree from 2.45 – 9.48 days post-burst are consistent with the lanthanides-rich macronova interpretation.
The origin of polarization in kilonovae and the case of the gravitational-wave counterpart AT 2017gfo

(Submitted on 11 Sep 2018 (v1), last revised 20 Nov 2018 (this version, v2))

The Gravitational Wave (GW) event GW 170817 was generated by the coalescence of two neutron stars (NS) and produced an electromagnetic transient, labelled AT 2017gfo, that was target of a massive observational campaign. Polarimetry, a powerful diagnostic tool for probing the geometry and emission processes of unresolved sources, was obtained for this event. The observed linear polarization was consistent with being mostly induced by intervening dust, suggesting that the intrinsic emission was weakly polarized ($P < 0.4 - 0.5\%$). In this paper, we present and discuss a detailed analysis of the linear polarization expected from a merging NS binary system by means of 3D Monte Carlo radiative transfer simulations assuming a range of possible configurations, wavelengths, epochs and viewing angles. We find that polarization originates from the non-homogeneous opacity distribution within the ejecta and can reach levels of $P \sim 1\%$ at early times (1–2 days after the merger) and in the optical $R$ band. Smaller polarization signals are expected at later epochs and/or different wavelengths. From the viewing-angle dependence of the polarimetric signal, we constrain the observer orientation of AT 2017gfo within $\sim 65^\circ$ from the polar direction. The detection of non-zero polarization in future events will unambiguously reveal the presence of a lanthanide-free ejecta component and unveil its spatial and angular distribution.

- Very appealing to the GW community, for better constraining the system configuration.
The FOReSeeable Future

• Is FORS becoming obsolete?
signs of tiredness?
FORS TOO Science too?

Target of Opportunity proposals per semester requesting FORS1 and/or FORS2

FORS1 last semester

FORSes
X-Shooter
Where do we go from here?

• FORS remains a chief instrument for ToO science at ESO (often also requested to compensate the unavailability of X-S)

• The imaging [and polarimetric] capabilities somehow balance out the spectral coverage of X-Shooter, but…

• There are indications of a loss-of-interest for ToO science with FORS, with a possible gradual “migration” to X-Shooter

• Ideally, one would like to have a ForShooter, combining spectral range, imaging and polarimetric capabilities all in one.
May the FORSes be with you
