Italy and Switzerland to Become Members of ESO

On 26 March the ESO Council, meeting in Geneva in special session, unanimously accepted Italy and Switzerland as new Member States in the Organization. This membership could become effective early in 1981, if the required parliamentary ratification procedure in the two countries will have been successfully completed.

According to the ESO Convention, new Member States have to pay a special contribution corresponding to their share in the investments made in the past. In fixing the amount of this contribution, the ESO Council also decided that it will be used to expand the observing facilities at La Silla. At present, these facilities are already heavily oversubscribed, and this could only become more so with a 25-per-cent increase in the user community. It is envisaged to build a 3.5-m telescope with a thin light-weight mirror, which could be completed within five years after final project approval. This telescope—the NTT (New Technology Telescope)—will give a much needed increase in the available large telescope observing time. Also, it will be valuable in obtaining the technological knowledge needed for the development of the large telescopes of the future, like the VLT. With the entry of Italy and Switzerland, ESO will be more able to fulfill one of its principal tasks, to foster cooperation in astronomy in Europe. We welcome our colleagues from these two countries and look forward with anticipation to their full participation in all ESO activities.

L. Woltjer
Director-General

Quasars Resolved

P. A. Wehinger, T. Gehren and S. Wyckoff

While observers have obtained spectra of more than 1,400 quasars since they were discovered in 1963, fewer than one per cent have been studied by direct imaging techniques at significantly faint surface brightness levels and high angular resolution to detect anything more than a bright point-like source. La
Silla's very dark sky, excellent seeing, plus the superb optics of the 3.6-m telescope have been combined with digital analysis of sky-limited photographs to produce two-dimensional intensity contour maps and image profiles of quasars. The contour maps reveal extended structure on a scale of 5-10 arc sec for 80 per cent of a sample of 20 low redshift (z = 0.1-0.5) quasars. In a significant number of cases the data also show the presence of galaxies near the QSO's, some of which have measured redshifts nearly equal to the QSO redshifts. This programme is the joint effort of Drs. Peter Wehinger and Thomas Gehren of the Max-Planck Institute for Astronomy in Heidelberg and Professor Susan Wyckoff of Arizona State University in Tempe, Arizona.

Although extensive spectroscopic and photometric observations have been obtained of some 1,400 known quasars, only a very limited number of QSO's have been observed through deep large-scale direct imaging (i.e. photography and/or other two-dimensional detectors). In order to understand the nature of quasars and their possible relation to Seyfert and N-type galaxies, to which they are often compared, we have undertaken a programme of direct imaging with the ESO 3.6-m telescope. The direct imaging data serve as essential guides for follow-up spectroscopic observations to determine the nature of the resolved structure and of the clustering of faint (20-22 mag) diffuse objects near the QSO's.

Two quasars already analysed both through direct imaging and spectroscopy are: Markarian 205 (A. Stockton, S. Wyckoff and P. A. Wehinger, 1979, Ap. J., 231, 673) at a redshift, z = 0.070, and the radio quasar 3C 206 (S. Wyckoff, P. A. Wehinger, H. Spinrad and A. Boksenberg, 1980, Ap. J. (in press)), at z = 0.200. These objects have been observed with the Mauna Kea 2.3-m telescope and the ESO 3.6-m telescope, respectively. The combined imaging and spectroscopic data from Mauna Kea show that Mark 205 (z = 0.070) is at its cosmological distance, unrelated to the foreground spiral galaxy, NGC 4319 (z = 0.006). Spectra of an optically resolved extension, 4 arc sec north-east of the QSO, show an absorption-line redshift equal to the emission-line redshift of the QSO. In fact, it has been shown that Mark 205 is simply the luminous nucleus of one of a pair of galaxies (z = 0.07) which lie nearly in the same line-of-sight as the spiral galaxy NGC 4319.

In the case of 3C 206 (= PKS 0837-120), we first secured electronographs at Mauna Kea of this luminous quasar which showed an extended elliptical envelope 18 arc sec diameter (along the major axis) and clustering of at least a dozen objects (of 20-22 mag) close to the quasar (P. A. Wehinger and S. Wyckoff, 1978, M.N.R.A.S., 184, 335). Then we obtained deeper and somewhat improved resolution photographs of 3C 206 with the ESO 3.6-m telescope at the prime focus. These illa-F plates (sensitized by baking in forming gas) were calibrated and subsequently were...
underlying galaxies are diffuse, while the QSO's are point sources, the galaxies have been difficult to detect.

Spectroscopic observations of the underlying galaxies around quasars, as well as associated cluster galaxies, are being obtained with the ESO 3.6-m and the Anglo-Australian Observatory 3.9-m telescopes. The observations employ fast Cassegrain spectrographs and Bokshenbergs Image Photon Counting System (IPCS). For 3C 206, one cluster galaxy has been observed (~20 mag, 12 arc sec north-east of the QSO) to have an absorption-line redshift, $z = 0.2026 ± 0.0015$, in close agreement with the emission-line redshift of the quasar ($z = 0.200$). A spectrum of the underlying structure, 3-6 arc sec west of the QSO, shows an absorption-line feature of CaII H and K and a low excitation emission-line spectrum at the same redshift as the QSO, as well as a redder continuum than that in the QSO.

The measured surface brightness, slope of the image profiles, angular diameters versus redshift, and emission- and absorption-line redshifts are leading to a consistent picture of quasars being the nuclei of distant active galaxies, some of which are located in clusters or groups of galaxies. Observations of the type we have described here need to be carried out for both radio QSO's and optical (radio-quiet) QSO's, and also for quasars with different redshifts found in

Richard M. West
unusual alignments by H. C. Arp. Through deep imaging and follow-up spectroscopy of extended sources associated with quasars we hope to derive a consistent picture of aso redshifts.

We are grateful to D. McMullan and K. Gyldenkerne for their interest and support in this programme, especially in regard to the earlier electronographic observations. The able assistance of members of the technical staff on La Silla is appreciated with thanks, especially of P. Bouchet, P. Giordan, J. Perez, and M. Pizarro.

ESO ST WORKSHOP No. 1:
Dwarf Galaxies:
The Need for Coordinated Space and Ground-based Observations
This workshop, which is the first in a series planned to encour­age European cooperation and coordination in the use of the space telescope, will take place on May 12–13 1980 in Geneva. Participation by invitation.
Information may be obtained from Prof. P. O. Lindblad, ESO Scientific Group, c/o CERN, CH-1211 Geneva 23, Switzerland.

Visiting Astronomers
April 1–October 1, 1980
Observing time has now been allocated for period 25 (April 1 to Oc­tober 1, 1980). As usual, the demand for telescope time was much greater than the time actually available.

The following list gives the names of the visiting astronomers, by tele­scope and in chronological order. The complete list, with dates, equipment and programme titles, is available from ESO/Munich.
